Any reproduction of this material, no matter whether as a whole or in parts, no matter whether in printed or in electronic form, requires explicit prior acceptance of the authors.

Automatic Testing Guidelines

Automatic unittesting requires you, as a student, to submit a notebook which contains strictly defined objects. Strictness of definition consists of unified shapes, dtypes, variable names and more.

Within the notebook, we provide detailed instruction which you should follow in order to maximise your final grade.

Name your notebook properly, follow the pattern in template name:

Assignment_N_NameSurname_matrnumber

- 1. N number of assignment
- 2. NameSurname your full name where every part of the name starts with a capital letter, no spaces
- 3. matrnumber your 8-digit student number on ID card (without k)

Example:

- Assignment_0_RenéDescartes_12345678
- ✓ Assignment_0_SørenAabyeKierkegaard_12345678
- X Assignment0_Peter_Pan_k12345678

Don't add any cells but use the ones provided by us. You may notice that most cells are tagged such that the unittest routine can recognise them.

We highly recommend you to develop your code within the provided cells. You can implement helper functions where needed unless you put them in the same cell they are actually called. Always make sure that implemented functions have the correct output and given variables contain the correct data type. Don't import any other packages than listed in the cell with the "imports" tag.

Note: Never use variables you defined in another cell in your functions directly; always pass them to the function as a parameter. In the unitest they won't be available either.

Good luck!

Task 1: AdaBoostM1 is an instance of forward stagewise modelling

In the lecture it was mentioned that one of the first boosting algorithms, i.e. AdaBoostM1, is equivalent to forward stagewise modelling using the exponential loss $L(y,g(\mathbf{x}))=\exp(-yg(\mathbf{x}))$ for a binary classification problem. In this task we intend to provide proof of this fact. We will guide you through the most important steps and you will have to add some details.

For AdaBoostM1, the basis functions at timestep n are the individual classifiers $b_n(\mathbf{x}) \in \{-1,1\}$. We assume that all of them are slightly better than random guessing. Note that we use b_n here for the resulting classifier at timestep n, which differs slightly from the notation in the slides, mainly to not confuse it with the corresponding approximation from forward stagewise modelling, which is also called g_n there.

Using the exponential loss in each timestep n we have to solve

$$(eta_n,b_n) = rg\min_{eta,b} \sum_{i=1}^l \exp(-y_i(g_{n-1}(\mathbf{x}_i) + eta b(\mathbf{x}_i)),$$

for the classifier b_n and the coefficient β_n which are added at each step. This can be rewritten as

$$(eta_n,b_n) = rg\min_{eta,b} \sum_{i=1}^l w_i^{(n)} \exp(-y_i eta b(\mathbf{x}_i)), \qquad (1)$$

with $w_i^{(n)} = \exp(-y_i g_{n-1}(\mathbf{x}_i))$. Since each $w_i^{(n)}$ depends neither on β nor b, it can be regarded as a weight that is applied to each observation. This weight depends on $g_{n-1}(\mathbf{x}_i)$, and so the individual weight values change with each iteration n. The solution of (1) can be found in two steps:

Calculation 1 (10 points):

In the **first step** fix $\beta \geq 0$ and show that in this case the solution to (1) is $b_n = \arg\min_b \sum_{i=1}^l w_i^{(n)} I(b(\mathbf{x}_i) \neq y_i)$. Hints:

1. Try to write the expressions in (1) after $\arg \min$ in the form

$$\sum_{b(\mathbf{x}_i)=y_i}(\dots) + \sum_{b(\mathbf{x}_i)
eq y_i}(\dots).$$

Find the right expressions for (...), such that the product $b(\mathbf{x}_i)y_i$ doesn't appear there anymore.

2. Now show that this can be written as

$$(\exp(\beta) - \exp(-\beta)) \sum_{b(\mathbf{x}_i) \neq y_i} w_i^{(n)} + \exp(-\beta) \sum_{i=1}^l w_i^{(n)}. \tag{2}$$
 The equation $\sum_i w_i^{(n)} = \sum_{b(\mathbf{x}_i) \neq y_i} w_i^{(n)} + \sum_{b(\mathbf{x}_i) = y_i} w_i^{(n)}$ might be helpful.

3. Argue why this already implies the claim.

Please provide reasoning and explanations in full sentences. Grading of the task will heavily depend on it.

Write your first step calculation here

1. Hint 1 ... $b(\mathbf{x}_i) \text{ and } y_i \text{ have either the value 1 or -1. So if } b(\mathbf{x}_i) = y_i \text{ then } -y_i b(\mathbf{x}_i) = -1.$ Otherwise $-y_i b(\mathbf{x}_i) = 1$. Therefore: $\sum_{i=1}^l w_i^{(n)} \exp(-y_i \beta b(\mathbf{x}_i)) = \sum_{b(x_i) = y_i} w_i^{(n)} exp(-\beta) + \sum_{b(x_i) \neq y_i} w_i^{(n)} exp(\beta)$

2. Hint 2 ..

3. Hint 3 ...

Then we have:
$$\sum_{b(x_i)=y_i} w_i^{(n)} exp(-\beta) + \sum_{b(x_i)\neq y_i} w_i^{(n)} exp(\beta) = exp(-\beta) \sum_{b(x_i)=y_i} w_i^{(n)} + exp(\beta) \sum_{b(x_i)\neq y_i} w_i^{(n)} = (exp(\beta) - exp(-\beta)) \sum_{b(x_i)\neq y_i} w_i^{(n)} + exp(-\beta) \sum_{i=1}^l w_i^{(n)}$$

 $rg \min_b (exp(eta) - exp(-eta)) \sum_{b(x_i)
eq y_i} w_i^{(n)} + exp(-eta) \sum_{i=1}^l w_i^{(n)}$ will be the same as $rg \min_b exp(eta) \sum_{b(x_i)
eq y_i} w_i^{(n)}$, because cases in which the classifier classified correctly don't increase the loss. $exp(eta) \sum_{b(x_i)
eq y_i} w_i^{(n)}$ can be written as

 $exp(\beta)\sum_{i=1}^l w_i^{(n)} I(b(\mathbf{x}_i) \neq y_i)$. Since β is fixed and not dependent on b, multiplication of the sum by $exp(\beta)$ will not affect the search for $arg \min_b$. Therefore:

$$rg\min_b exp(eta) \sum_{i=1}^l w_i^{(n)} I(b(\mathbf{x}_i)
eq y_i) = rg\min_b \sum_{i=1}^l w_i^{(n)} I(b(\mathbf{x}_i)
eq y_i)$$

Calculation 2 (20 points):

In the **second step** you need to optimize the following expression with respect to β :

$$(\exp(eta)-\exp(-eta))\sum_{b_n(\mathbf{x}_i)
eq y_i}w_i^{(n)}+\exp(-eta)\sum_{i=1}^lw_i^{(n)}$$

Hint: do it in the usual way (i.e. by differentiating the expression and setting it to 0).

Using the abbreviation $\operatorname{err}_n = \frac{\sum_{i=1}^l w_i^{(n)} I(y_i \neq b_n(\mathbf{x}_i))}{\sum_{i=1}^l w_i^{(n)}}$ show that the obtained expression is $\beta_n = \frac{1}{2} \ln \frac{1 - \operatorname{err}_n}{\operatorname{err}_n}$.

Note that $\beta_n \geq 0$, by our assumption that all classifiers are better than random guessing, i.e. $\text{err}_n \leq \frac{1}{2}$, so the result is in accordance with the previous subtask.

Please provide reasoning and explanations in full sentences. Grading of the task will heavily depend on it.

Write your second step calculation here

To Derivate ... $rac{\partial}{\partial eta}(\exp(eta) - \exp(-eta)) \sum_{b_n(\mathbf{x}_i)
eq y_i} w_i^{(n)} + \exp(-eta) \sum_{i=1}^l w_i^{(n)} = (\exp(eta) + \exp(-eta)) \sum_{i=1}^l w_i^{(n)}$

2. Using given abbreviation show ...

$$(\exp(eta)+\exp(-eta))\sum_{b_n(\mathbf{x}_i)
eq y_i}w_i^{(n)}-\exp(-eta)\sum_{i=1}^lw_i^{(n)}=0$$

$$(\exp(eta)+\exp(-eta))\sum_{b_n(\mathbf{x}_i)
eq y_i}w_i^{(n)}=\exp(-eta)\sum_{i=1}^lw_i^{(n)}$$

$$(exp(eta - (-eta)) + exp(-eta - (-eta))) \sum_{b_n(\mathbf{x}_i)
eq u_i} w_i^{(n)} = \sum_{i=1}^l w_i^{(n)}$$

$$(exp(2eta)+1) \sum_{b_n(\mathbf{x}_i)
eq y_i} w_i^{(n)} = \sum_{i=1}^l w_i^{(n)}$$

$$exp(2eta) = rac{\sum_{i=1}^{l} w_i^{(n)}}{\sum_{b_n(\mathbf{x}_i)
eq j_i} w_i^{(n)}} - 1$$

$$exp(2eta)=rac{1}{err_n}-1=rac{1-err_n}{err_n}$$

$$2eta=lnrac{1-err_n}{err_n}$$

$$eta = rac{1}{2} ln rac{1-err_n}{err_n}$$

Therfore:

$$eta_n = rac{1}{2} ln rac{1 - err_n}{err_n}$$

Calculation 3 (10 points):

In the **final step** we can update the approximation as follows: $g_n(\mathbf{x}) = g_{n-1}(\mathbf{x}) + \beta_n b_n(\mathbf{x})$. To finish the proof proceed by deriving the following relations:

1. The weights for the next generation can be computed as follows:

$$w_i^{(n+1)} = w_i^{(n)} \exp(-y_i \beta_n b_n(\mathbf{x})).$$

2.
$$-y_ib_n(\mathbf{x})=2I(y_i
eq b_n(\mathbf{x}_i))-1$$

3. Use these two relations to show that:

$$w_i^{(n+1)} = w_i^{(n)} \exp(-eta_n) \exp(lpha_n I(y_i
eq b_n(\mathbf{x}_i))) \hspace{1cm} (2)$$

where $\alpha_n=2\beta_n$ is the α_n from the AdaBoostM1 algorithm from the lecture.

Please provide reasoning and explanations in full sentences. Grading of the task will heavily depend on it.

Write your final step calculation here

1. Calculate weights ...

$$w_i^{(n)} = \exp(-y_i g_{n-1}(\mathbf{x}_i))$$

$$w_i^{(n+1)} = \exp(-y_i g_n(\mathbf{x}_i))$$

Then I use the relation between $g_n(\mathbf{x}_i)$ and $g_{n-1}(\mathbf{x}_i)$:

$$w_i^{(n+1)} = \exp(-y_i(g_{n-1}(\mathbf{x}) + eta_n b_n(\mathbf{x}))) = \exp(-y_i g_{n-1}(\mathbf{x}_i)) \exp(-y_i eta_n b_n(\mathbf{x}))$$

```
Then I use the fact that w_i^{(n)}=\exp(-y_ig_{n-1}(\mathbf{x}_i)): w_i^{(n+1)}=w_i^{(n)}\exp(-y_i\beta_nb_n(\mathbf{x})) 2. ... If b(\mathbf{x}_i)=y_i then I(y_i\neq b_n(\mathbf{x}_i))=0 and -y_ib(\mathbf{x}_i)=-1, so -y_ib(\mathbf{x}_i) can be written as -y_ib(\mathbf{x}_i)=2I(y_i\neq b_n(\mathbf{x}_i))-1. Otherwise, when b(\mathbf{x}_i)\neq y_i, I(y_i\neq b_n(\mathbf{x}_i))=1 and -y_ib(\mathbf{x}_i)=1, so -y_ib(\mathbf{x}_i) can be written as -y_ib(\mathbf{x}_i)=2I(y_i\neq b_n(\mathbf{x}_i))-1. Therefore -y_ib(\mathbf{x}_i)=2I(y_i\neq b_n(\mathbf{x}_i))-1 in any case. 3. ... w_i^{(n+1)}=w_i^{(n)}\exp(-y_i\beta_nb_n(\mathbf{x})). \text{ can be written as } w_i^{(n+1)}=w_i^{(n)}\exp(-y_ib_n(\mathbf{x})\beta_n). Since -y_ib(\mathbf{x}_i)=2I(y_i\neq b_n(\mathbf{x}_i))-1, we can substitute it to the equation: w_i^{(n+1)}=w_i^{(n)}\exp((2I(y_i\neq b_n(\mathbf{x}_i))-1)\beta_n). \text{ Then:} w_i^{(n+1)}=w_i^{(n)}\exp((2I(y_i\neq b_n(\mathbf{x}_i))-1)\beta_n)=w_i^{(n)}\exp(2\beta_nI(y_i\neq b_n(\mathbf{x}_i))-\beta_n). Using the properties of exponential function: w_i^{(n+1)}=w_i^{(n)}\exp(2\beta_nI(y_i\neq b_n(\mathbf{x}_i))-\beta_n)=w_i^{(n)}\exp(-\beta_n)\exp(2\beta_nI(y_i\neq b_n(\mathbf{x}_i))). Because \alpha_n=2\beta_n, we get: w_i^{(n+1)}=w_i^{(n)}\exp(-\beta_n)\exp(\alpha_nI(y_i\neq b_n(\mathbf{x}_i))).
```

Task 2: Random Forests and Feature importance

In this task you will train a Random Forest (RF) Classifier on a subset of fashionMNIST. You should observe how these models can immediately give you useful information about feature importance, which is a very convenient property of RFs.

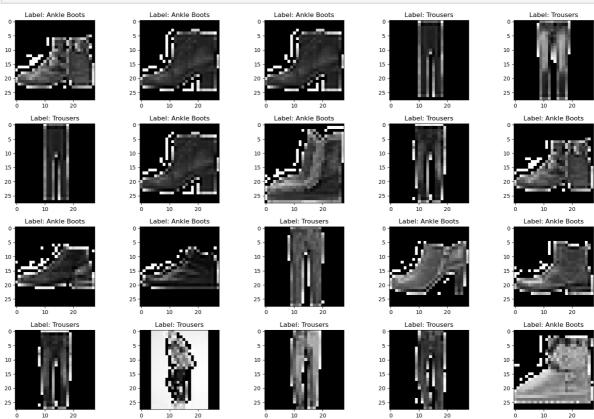

First you should re-use the given code from the previous assignment to load the whole data set (the procedure is completely analogous).

- Next implement code that filters the data set for the classes with labels 1 (trousers) and 9 (ankle boots). You should create the filtered train data set from x_train and y_train and the test data set from x_test and y_test.
 - **Hint**: Masks provide a convenient solution to this task.
- After the filtering procedure the data samples corresponding to trousers should be labelled as 1 and the ankle boots as 0. Perform this step on the test and train data set.
- To accomplish this task, implement a function **_filter_()**.

Code 1 (15 points):

```
import seaborn as sns
         from sklearn.metrics import accuracy_score, confusion_matrix
         # Set random seed to ensure reproducible runs
         RSEED = 10
In [21]: #Load training and test data (routine from last week)
         data = MNIST('./dataset/')
         img_train, labels_train = data.load_training()
         x_train = np.array(img_train)
         y_train = np.array(labels_train)
         x_test,y_test = data.load_testing()
         x_{test} = np.array(x_{test})
         y_test = np.array(y_test)
         print(y_train)
         print(y_test)
         [2 9 6 ... 8 8 7]
         [0 1 2 ... 8 8 1]
         """Function _filter_() is created to filter datasets w.r.t to given labels
In [22]:
         @param x_train Training feature matrix
         @param y_train Training labels vector
         @param x_test Test feature matrix
         @param y_test Test labels vector
         @param labels_list list of length 2 which consists of integer labels.
         @returns a tuple (x_train_filtered, y_train_filtered, x_test_filtered, y_test_filtered)
         def _filter_(x_train:np.array,
                       y_train:np.array,
                       x_test:np.array,
                       y_test:np.array,
                       labels_list:list):
             #Your code goes here ↓↓↓
             ytr = y_train[np.in1d(y_train,labels_list)]
             yts = y_test[np.in1d(y_test,labels_list)]
             x_train_filtered = x_train[np.in1d(y_train,labels_list)]
             y_train_filtered = np.where(ytr ==9, 0, ytr)
             x_test_filtered = x_test[np.in1d(y_test,labels_list)]
             y_test_filtered = np.where(yts ==9, 0, yts)
             #Your code ends here _
              return (x train filtered, y train filtered, x test filtered, y test filtered)
In [23]: #NOTHING TO CHANGE HERE
         x_train, y_train, x_test, y_test = _filter_(x_train, y_train, x_test, y_test, [1,9]
         print(y train)
         print(y_test)
         [0 0 0 ... 0 0 1]
         [1 1 1 ... 0 0 1]
         In the following we visualize a few randomly selected samples from our training data:
In [24]: #A routine that you can use for plotting some of the data.
         arr = ['Ankle Boots','Trousers']
         a = np.random.randint(1,40,20)
         plt.figure(figsize=(20, 13))
```

```
for n,i in enumerate(a):
    plt.subplot(4, 5, n+1)
    two_d = (np.reshape(x_train[i], (28, 28)) * 255).astype(np.uint8)
    plt.title('Label: {0}'.format(arr[y_train[i]]))
    plt.imshow(two_d, interpolation='nearest',cmap='gray')
plt.subplots_adjust(hspace = 0.3)
```

Code (5 points):

Your task now is to train a sklearn RandomForestClassifier with the default parameters on the training data set.

Then get the model's predictions for the test data set. Use **RSEED** as random_seed for the RandomForestClassifier.

For this, we ask you to implement a function fit_predict.

```
return model, prediction
```

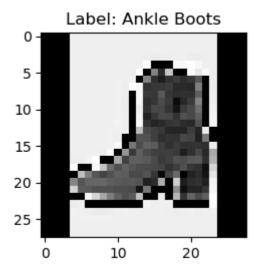

```
In [26]: model, prediction = fit_predict(x_train,y_train,x_test,y_test, RSEED)
```

Code (15 points):

Now, within variables size_test, num_wrong save the size of the test set and number of misclassified test samples. Both variables should be integers. Retrieve misclassified samples from test set and save them as a list items wrong.

Use your predictions to plot up to 20 test data sample(s) that were **missclassified**:

```
In [27]: #NUMBER OF WRONG PREDICTIONS
         #Your code goes here ↓↓↓
         size\_test = len(y\_test)
         num wrong = np.sum(y test != prediction).astype(np.uint8)
         items_wrong = x_test[np.where(y_test != prediction)]
         #Your code ends here
         #Following print statement might be evaluated
         print("Number of test samples: {0}\nNumber of misclassified samples: {1}".format(s
         Number of test samples: 2000
         Number of misclassified samples: 1
In [28]:
         #PLOTTING WRONG PREDICTIONS
         #Your code goes here ↓↓↓
         #Use your freestlye plotting, or routine we have shown above
         arr = ['Ankle Boots','Trousers']
         a2 = np.where(y_test != prediction)
         a2 = a2[0:20]
         plt.figure(figsize=(20, 13))
         for n,i in enumerate(a2):
             if(len(a2)==1):
                  i = i[0]
             plt.subplot(4, 5, n+1)
             two_d = (np.reshape(x_test[i], (28, 28)) * 255).astype(np.uint8)
             plt.title('Label: {0}'.format(arr[y_test[i]]))
             plt.imshow(two_d, interpolation='nearest',cmap='gray')
         plt.subplots_adjust(hspace = 0.3)
         #Your code ends here
```

Code (20 points):

Within this part we will try to see the decision-making incentives of Random Forest.

To do this we ask you to implement the following tasks:

- Take your training dataset and split it into 2: trousers and boots.
 Calculate the average of features. Reshape averages the to 2D arrays of shape 28*28 and plot them as heatmaps. Save results under variables tr_av and bo_av
- 2. From the average of trousers subtract the average of boots. Save result as a variable **diff**. Plot it as a heatmap.
- 3. Define the feature importance of the previously trained RF classifier witin variable **importances**. Visualize it as a heatmap.

Hint: Check scikit-learn documentation to access feature importance.

The evaluation of the following code will be done by viewing your plots.

For those who are curious: run RF under different seeds, and look how plots are changing. BEFORE SUBMISSION RETURN TO ORIGINAL SEED = 10

```
#PLOTTING HEATMAPS

#Your code goes here \| \| \| \|
#Use your freestlye plotting
#No plots' variables are needed

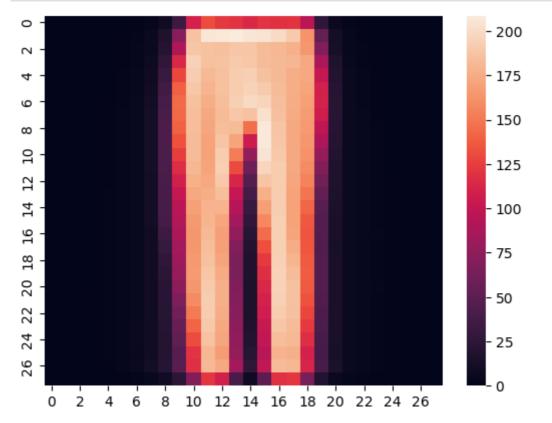

#Step 1 Split and calculate averages

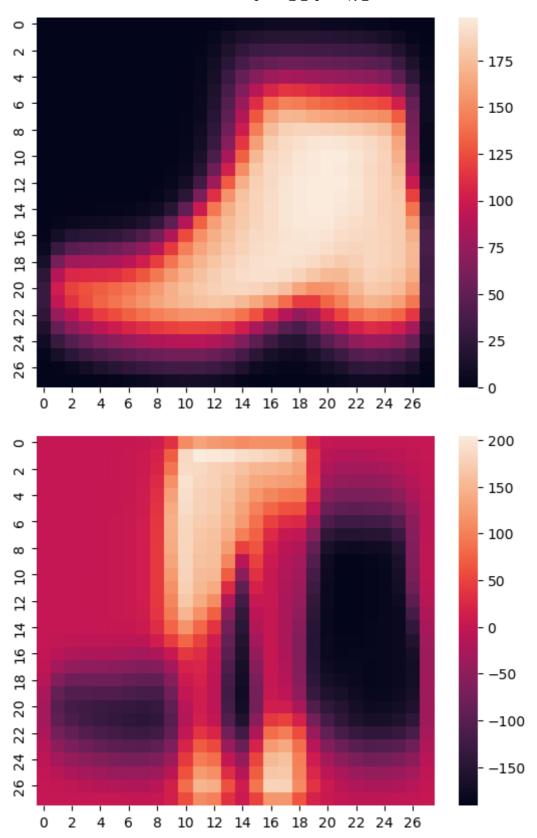

tr = x_train[y_train == 1]
bo = x_train[y_train == 0]

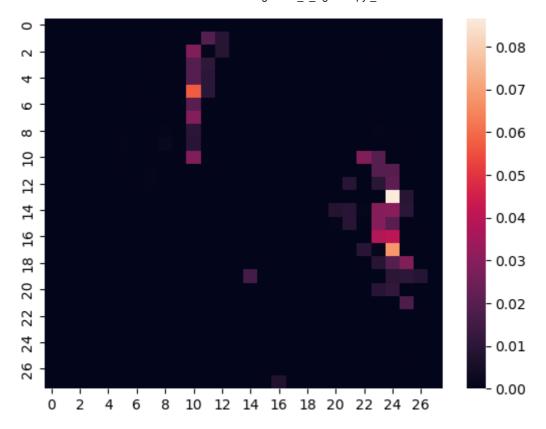

tr_av = np.mean(tr, axis=0)
bo_av = np.mean(bo, axis=0)

tr_av = np.reshape(tr_av, (28, 28))
bo_av = np.reshape(bo_av, (28, 28))
sns.heatmap(tr_av)
plt.show()
```

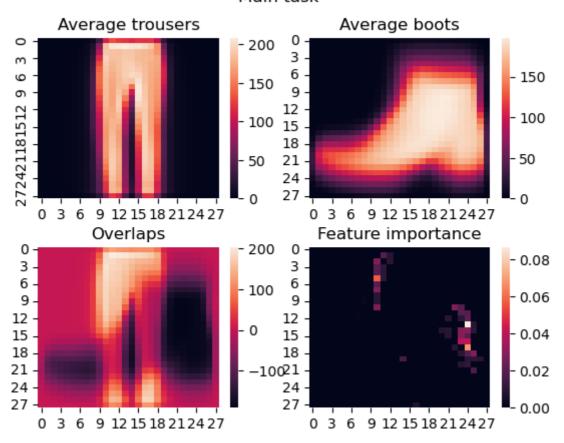

```
sns.heatmap(bo_av)
plt.show()
#Step 2 Subtract
diff = np.subtract(tr_av,bo_av)
sns.heatmap(diff)
plt.show()
#Step 3 Extract feature importance
importances = model.feature_importances_
importances = np.reshape(importances, (28, 28))
sns.heatmap(importances)
plt.show()
#Step 4 plot everything together
htmaps = [tr_av,bo_av,diff,importances]
titles = ['Average trousers','Average boots','Overlaps','Feature importance']
fig, axes = plt.subplots(2, 2)
fig.suptitle("Main task")
for n,i in enumerate(htmaps):
   sns.heatmap(data =i,ax=axes[n//2, n%2]).set_title(titles[n])
   plt.subplots_adjust(hspace = 0.3)
#Your code ends here _
```

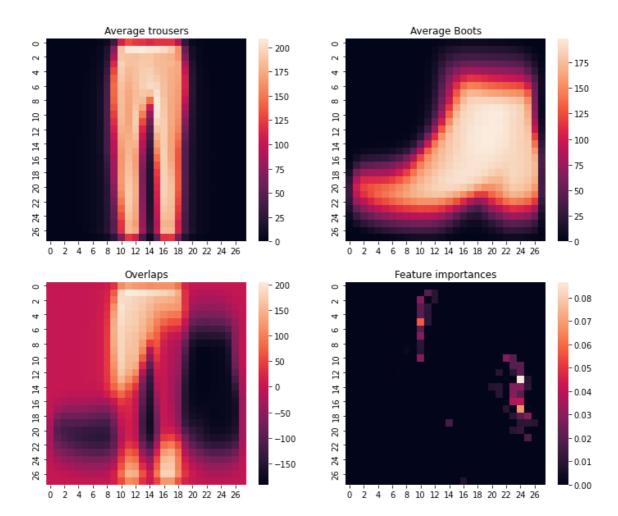

If you have solved the previous task correctly, the resulting plot should look close to this:

Main Task

Question (5 points):

What observations can you make? (Multiple answers might be correct)

To answer the question assign to variables in the nex cell **True** or **False** boolean values. To earn points **assign values to all variables**.

NOTE Do not reuse these variable names. They are used for testing.

- a) RF achieves accuracy lower than 85%
- b) The most important features are located in image regions that primarily show either only trousers or ankle boots as depicted by the plots of average trousers and boots.
- c) If one pixel would always be bright for trousers but never for ankle boots the RF classifier would certainly learn to use only this pixel as one of the features.
- d) Comparing the misclassified ankle boot to other ankle boots suggests that it might be an outlier in terms of background brightness.

```
In [30]: #examples for you
    example_of_true_variable = True
    example_of_false_variable = False

#your answers go here \limits \limits
a_=False
```

```
b_=True
c_=True
d_=False
```

```
